AB Antiseptic compns. comprise at least one salt of EDTA are disclosed. These compns. have broad spectrum antimicrobial and antifungal activity and they also have anticoagulant properties. The antiseptic compns. have also demonstrated activity in penetrating and breaking down microbial slime, or biofilms. They are safe for human and medical uses and may be used as prophylactic preps. to prevent infection, or to reduce the

proliferation of and/or eliminate existing or established infections. On testing tetra- and tri-sodium EDTA were chosen as the most promising candidates. Solns. of these salts were used to disinfect catheters.

AB Disclosed is a disinfection method using an antiseptic solution having an aqueous

medium and hydrogen peroxide dissolved therein, characterized in that the antiseptic solution is accommodated in a container so as to have a depth of 3 to 10 mm, an article to be disinfected is immersed in the antiseptic solution, and then the antiseptic solution is irradiated with a light having a wave length of 280 to 385 nm at least in the direction of its depth, to thereby disinfect the article to be disinfected. The disinfection method can be carried out with ease and simplicity, and also exhibits excellent disinfecting effect.

AB A skin care and/or cosmetic composition with antiseptic-type antibacterial activity for applying on a damaged or healthy skin is described, characterized in that it is in the form of an oil-in-water emulsion containing a basic chlorhexidine in the oil phase of said emulsion and a chlorhexidine salt in the aqueous phase of the emulsion, the total chlorhexidine concentration being 0.05% to 1% by weight, and containing 0.025% to 1% by weight of a chelating agent such a polyaminocarboxylic acid or a salt thereof. A cosmetic emulsion contained ethylene glycol stearate 5.450, stearic acid 3.625, cetyl palmitate 0.350, solid paraffin 1.600, light liquid paraffin 6.850, perhydrosqualene 1.500, avocado oil 1.000, propylene glycol 2.300, sodium and trolamine alginate 0.134, disodium EDTA 0.100, benzyl alc. 0.200, chlorhexidine 0.023, 20% solution of chlorhexidine digluconate 0.725, and water q.s. 100%.

AB An antiseptic based on a 4-chloro-3,5-xyleneol-sodium EDTA mixture [63688-38-0] was more effective against Escherichia coli, Pseudomonas aeruginosa, and Proteus vulgaris than were 2 other com. available antiseptics containing chlorhexidine gluconate [18472-51-0] or a cetrimide-chlorhexidine mixture [63688-37-9]). The chloroxylenol-EDTA antiseptic was most active both when tested on skin and when tested in vitro according to the method of Kelsey and Sykes (1969). The skin test indicated that this antiseptic possessed the greatest bactericidal activity against all 3 gram-neg. microorganisms with regard to both immediate and persistent effects.

AB The bactericidal activity of RBA 777 (a product containing 4.8% 4-chloro-3,5-xyleneol (I) [88-04-0] varied with both the cultural and environmental test conditions against *Pseudomonas aeruginosa* and to a lesser extent against *Staphylococcus aureus*. The addition of EDTA to RBA 777 improved the activity as confirmed in vivo. Previous reports have already illustrated this potential and the present evaluations of the new antibacterial agent DA 136 (a product containing I and disodium EDTA) [58798-60-0] confirmed these results to its performance under adverse conditions, often associated with the hospital environment.

AB A microtiter plate assay was employed to systematically assess the
interaction between EDTA (EDTA) or lactoferrin and nisin, lysozyme, or
monolaurin against strains of *Listeria monocytogenes*, *Escherichia coli*,
Salmonella enteritidis, and *Pseudomonas fluorescens*. Low levels of EDTA
acted synergistically with nisin and lysozyme against *L. monocytogenes* but
EDTA and monolaurin interacted additively against this microorganism.
EDTA synergistically enhanced the activity of nisin, monolaurin, and
lysozyme in tryptic soy broth (TSB) against two enterohemorrhagic *E. coli*
strains. In addition, various combinations of nisin, lysozyme, and
monolaurin with EDTA were bactericidal to some
gram-neg. bacteria whereas none of the antimicrobials alone were
bactericidal. Lactoferrin alone (2000 µg ml⁻¹) did not inhibit any of
the bacterial strains, but did enhance nisin activity against both *L.*
monocytogenes strains. Lactoferrin in combination with monolaurin
inhibited growth of *E. coli* O157:H7 but not *E. coli* O104:H21. While
lactoferrin combined with nisin or monolaurin did not completely inhibit
growth of the gram-neg. bacteria, there was some growth inhibition. All
combinations of EDTA or lactoferrin with antimicrobials were less
effective in 2% fat UHT milk than in TSB. *S. enteritidis* and *P.*
fluorescens strains were consistently more resistant to antimicrobial
combinations. Resistance may be due to differences in the outer membrane
and/or LPS structure.

AB When used in combination with chelating agents (EDTA, EGTA, citrate, phosphate), the bacteriocin nisin is effective for reducing populations of gram-neg. bacteria in vitro. This study examined parameters (buffers, temperature presence of divalent cations) that affect nisin inhibition of Escherichia coli O157:H7 and Salmonella typhimurium. Approx. 7 log10 colony-forming units (CFU) per mL of E. coli and S. typhimurium were treated in PBS or MOPS buffers containing 50 µg/mL of purified nisin, alone or in combination with 500 mM lactate, 100 mM citrate, 50 mM EDTA, and 1% (wt/vol) sodium hexametaphosphate (pH 7.0) at 37°C for 60 min or 5°C for 30 min. Surviving bacterial populations were compared to untreated controls (buffers without nisin). Data indicated that treatments with nisin in buffers resulted in redns. of 4.30 and 2.30 log10 CFU/mL of E. coli and S. typhimurium, resp., as compared to untreated controls. Population redns. ranging from 2.29 to 5.49 log10 CFU/mL were observed when cells were treated with nisin and chelator combinations at either 37°C for 60 min or 5°C for 30 min. The addition of magnesium and calcium to buffers with nisin decreased inhibition. Data obtained from spectrophotometric expts. indicated that treatments caused release of cellular constituents. However, transmission electron microscopy (TEM) analyses were inconclusive, since cellular membranes did not appear to be disrupted.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB Pectate lyase (PL) is the principal or sole enzyme responsible for maceration of plant tissue caused by most strains of soft-rotting pseudomonads. Production of PL in four out of 25 *Pseudomonas fluorescens* (or *P. marginalis*) strains examined was not induced by the enzyme substrate, polygalacturonate (PGA), but was induced by Ca^{2+} . These four strains produced 10 times more PL in medium containing 1 mM CaCl_2 than in one containing no CaCl_2 supplement. Over 86% of total PL produced by these strains in CaCl_2 -supplemented medium was excreted into the culture fluid. Only a small portion (13%) of total PL produced by these strains in CaCl_2 -deficient medium was detected in the extracellular fraction. Ca^{2+} thus affected not only the amount but also the final destination of PL produced by these pseudomonads. Addnl., all four strains were unable to use PGA as a nutritional source when cultured in Ca^{2+} -deficient medium, which indicates that the initial step of PGA degradation was mediated by Ca^{2+} -dependent PL and not by Ca^{2+} -independent polygalacturonase. The optimal Ca^{2+} concentration required for PL production in one of these strains, CY091, was determined to be 0.2 mM. A linear correlation was observed between the amts. of PL produced and the concns. of Ca^{2+} included in the medium. Furthermore, the requirement of Ca^{2+} for PL induction could be replaced by Sr^{2+} but not by other divalent cations, such as Zn^{2+} , Fe^{2+} , Mn^{2+} , Mg^{2+} , and Ba^{2+} . Because of the indispensable role of Ca^{2+} in PGA degradation and in PL production, the possibility of using the ion-chelating agent EDTA for control of *Pseudomonas* rot was evaluated. **EDTA** exhibited **bactericidal** activity against *P. fluorescens* at a minimal inhibitory concentration of 4 mM. When assayed on potato tuber disks, EDTA at a concentration of 0.13 mM (40 ppm), which is 30-fold lower than the minimal inhibitory concentration, was effective in preventing *P. fluorescens* from growing and causing maceration in potato tuber tissue.

AB The effectiveness of alkaline builders as potentiators of the bactericidal activity of didecyldimethylammonium chloride (I)/polyoxyethylene alkyl ether (AE, surfactant) mixts. against *Staphylococcus* (S.) aureus and *Escherichia* (E.) coli was quant. studied by determination of the viable bacterial

counts obtained by exposure to the solns. containing I of the filter-paper strips on which the test organisms were inoculated and dried. EDTA potentiated the activity of I/AE against both organisms but Na_2SiO_3 did not. Other builders, carbonates, bicarbonates, and citrates, were effective in potentiating the activity against *S. aureus* and *E. coli*. Effects of various surfactants on the bactericidal activity of I in the presence of EDTA was studied similarly. AEs decreased the activity of I independent of the oxyethylene number (6-18), and their antagonistic effects depended on the I/AE ratio (1:0-1:3). Based the antagonistic effects, the surfactants could be classified into 3 groups: (1) ethylene oxide-propylene oxide copolymer had no effect; (2) alkyl amine oxide, N-lauryl betaine, alkyl amidopropyl betaine, and polyhexyethylene/polyoxypropylene cetyl ether had weak effects; and (3)

polyoxyethylene alkyl ether had strong effects.

AB Nisin, produced by *Lactococcus lactis lactis*, has a broad spectrum of activity against gram-pos. bacteria and is generally recognized as safe in the United States for use in selected pasteurized cheese spreads to control the outgrowth and toxin production of *Clostridium botulinum*. This study evaluated the inhibitory activity of nisin in combination with a chelating agent, disodium EDTA, against several *Salmonella* species and other selected gram-neg. bacteria. After a 1-h exposure to 50 µg of nisin per mL and 20 mM disodium EDTA at 37°, a 3.2- to 6.9-log-cycle reduction in population was observed with the species tested. Treatment with disodium EDTA or nisin alone produced no significant inhibition (<1-log-cycle reduction) of the *Salmonella* and other gram-neg. species tested. These results demonstrated that nisin is bactericidal to *Salmonella* species and that the observed inactivation can be demonstrated in other gram-neg. bacteria. Applications involving the simultaneous treatment with nisin and chelating agents that alter the outer membrane may be of value in controlling food-borne salmonellae and other gram-neg. bacteria.

AB The adsorption of mixts. of cationic surfactants (alkylpyridinium chlorides, hexadecyltrimethylammonium chloride) with Na-EDTA on *E. coli* and well-defined model adsorbates (hydrophilic and hydrophobic colloidal and porous silicas) was studied to elucidate the mechanisms of surfactant-EDTA synergism observed during the preservation of aqueous drug preps. Thus, the adsorption of EDTA²⁻ ions into neg.-charged surfaces was mediated by surfactant cations by a counterion-binding mechanism on hemimicelles formed by previous surfactant adsorption. Neutral electrolytes (NaCl) enhanced surfactant adsorption; Cl⁻ ions reduced EDTA²⁻ counterion sorption onto the hemimicelles by competing for available sites. The synergistic effect previously mentioned is believed a consequence of this coadsorption phenomenon.

AB Nisin compns. containing nonbactericidal agents have enhanced, broad-range
 bactericidal activity against gram-neg. and gram-pos. bacteria than nisin
 alone. Thus, nisin (30 µg/mL) containing 20 mM EDTA had a superior

activity against *Salmonella typhimurium* (a synergistic activity of >1000 times than that of nisin alone). Addition of Tween 20 (1%) further enhanced the activity of nisin and EDTA.

AB The role of turkey complement in a serum bactericidal reaction was determined using serum-sensitive and serum-resistant *Escherichia coli* isolated from turkeys. Inactivation of complement by heating serum (56° for 40 min) or by treating serum with 10 mM **EDTA** eliminated **bactericidal** activity. Serum-sensitive *E. coli* organisms were killed by turkey serum treated with 10 mM ethylene glycol-bis- β -(aminoethyl ether)-N,N,N',N'-tetraacetic acid and 5 mM MgCl₂. Exposure of normal turkey serum to serum-sensitive or serum-resistant *E. coli* resulted in equivalent redns. in hemolytic activity of serum. Treatment of serum-resistant *E. coli* with antibody rendered the bacteria sensitive to bactericidal effects of normal turkey serum. Serum-sensitive *E. coli* organisms were readily killed by an alternative complement pathway, serum-sensitive and serum-resistant *E. coli* activated the complement system equally well, and antibody was required for complement-mediated killing of certain serum-resistant *E. coli* organisms from turkeys.

CODEN: JDSCAE; ISSN: 0022-0302
DOCUMENT TYPE: Journal
LANGUAGE: English

AB Antimicrobial activities of 3 phenolic compds. and 4 metal chelators were tested at 0, 250, 500, and 1000 ppm in vitro against 4 major mastitis-causing bacteria, *Streptococcus agalactiae*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, and *Escherichia coli*. Overall, butylated hydroxyanisole and tert-butylhydroquinone showed the greatest antimicrobial activity. These phenolics were bactericidal at 250-500 ppm against all 4 bacteria tested. The butylated hydroxytoluene was bactericidal against the gram-pos. bacteria but was ineffective against the coliforms. At 250 ppm, di-Na **EDTA** was **bactericidal** against the gram-pos. bacteria but much less effective against the gram-neg. ones. However, diethylenetriaminepentaacetic acid was more growth inhibitory than EDTA against the gram-neg. bacteria and especially against *E. coli*. All other compds. were generally much less effective or ineffective against all 4 microorganisms. Therefore, butylated hydroxyanisole, butylated hydroxytoluene, tert-butylhydroquinone, EDTA, and diethylenetriaminepentaacetic acid may have practical implications in the prevention or treatment of bovine mastitis.

DOCUMENT TYPE: Journal
LANGUAGE: English
AB The relative roles of Kupffer cell, complement, and specific antibody in liver antimicrobial activities were investigated by using a rat liver perfusion model. Normal livers trapped an average of 60% of Salmonella typhimurium in a single pass and in the presence of plasma killed >60% of these organisms in 30 min. Livers depleted of Kupffer cell function by silica treatment had significantly less bactericidal ability (ca. 15%) in the presence of plasma, showing that viable Kupffer cells are required for optimal antimicrobial activity. To determine the importance of complement in Salmonella killing, plasma complement activity was inhibited by heating at 57 and 50°, zymosan adsorption, chelation with disodium EDTA and depletion of rat C3 by using specific immunoadsorbent. All treatments significantly reduced bactericidal activity in the perfused liver. Chelation of plasma with EDTA had no effect, suggesting that the alternate and not the classical pathway for complement activation was involved. Immune plasma alone was bactericidal. When immune plasma was heated, zymosan adsorbed, or chelated with **EDTA, bactericidal** activity was inhibited in the perfused liver, but bacterial trapping increased. These results suggest that complement is required for bactericidal activity in perfused livers and that specific antibody only enhances bacterial trapping.

PRIORITY APPLN. INFO.:

AB Salts of bisbiguanides with sequestering amino acids showed improved water solubility and increased bactericidal activity compared with the free bases. Thus, N-(hydroxyethyl)ethylenediaminetriacetic acid chlorhexidine salt (I) [40497-97-0], dissolved in water with aid of cetyltrimethylammonium bromide [57-09-0], was bactericidal toward *Pseudomonas aeruginosa* at 90 ppm. The salts may be used as disinfectants or applied topically, orally, perlingually, or rectally.

AB A composition with bactericidal properties comprises a synergistic mixture of di-Na ethylenediaminetetraacetic acid-2H₂O (I) with the quaternary pyrrolinium tartrate (II). The composition also shows antifungal and antitrichomonal properties and has topical applications in dermatol., ophthalmol., and gynecol. A composition contains 200 mg II and 100 mg I in distilled H₂O.

AB Pseudomonas aeruginosa was treated with EDTA at pH 9.2 and 7.1 and the
effects on the bacteria were compared. The loss of viability and leakage
of intracellular solutes were proportional to the release of
lipopolysaccharide from the cell wall. Results of similar tests using
other chelating agents supported this conclusion and indicated that Mg²⁺
were specifically involved. High-mol.-weight solutes extracted by EDTA at pH
9.2 constituted .apprx.30 of the dry weight of the cells treated. About 45 of
the material in the extract was separated as a complex, believed to come from
the cell wall which had the approx. composition: protein, 60, lipopolysaccharide,
30, loosely bound lipid, 10. Although the complex was apparently
heterogeneous in both size and composition, its components were not separated
by electrophoresis, gel filtration, or anion-exchange chromatog. Possible
forms of association between components of the complex were examined

AB A microtiter plate assay was employed to systematically assess the interaction between ethylenediaminetetraacetic acid (EDTA) or lactoferrin and nisin, lysozyme, or monolaurin against strains of *Listeria monocytogenes*, *Escherichia coli*, *Salmonella enteritidis*, and *Pseudomonas fluorescens*. Low levels of EDTA acted synergistically with nisin and lysozyme against *L. monocytogenes* but EDTA and monolaurin interacted additively against this microorganism. EDTA synergistically enhanced the activity of nisin, monolaurin, and lysozyme in tryptic soy broth (TSB) against two enterohemorrhagic *E. coli* strains. In addition, various combinations of nisin, lysozyme, and monolaurin with **EDTA** were **bactericidal** to some gram-negative bacteria whereas none of the antimicrobials alone were bactericidal. Lactoferrin alone (2000 microg ml(-1)) did not inhibit any of the bacterial strains, but did enhance nisin activity against both *L. monocytogenes* strains. Lactoferrin in combination with monolaurin inhibited growth of *E. coli* O157:H7 but not *E. coli* O104:H21. While lactoferrin combined with nisin or monolaurin did not completely inhibit growth of the gram-negative bacteria, there was some growth inhibition. All combinations of EDTA or lactoferrin with antimicrobials were less effective in 2% fat UHT milk than in TSB. *S. enteritidis* and *P. fluorescens* strains were consistently more resistant to antimicrobial combinations. Resistance may be due to differences in the outer membrane and/or LPS structure.

AB The role of turkey complement in a serum bactericidal reaction was determined using serum-sensitive and serum-resistant *Escherichia coli* isolated from turkeys. Inactivation of complement by heating serum (56 C for 40 minutes) or by treating serum with 10 mM **EDTA** eliminated **bactericidal** activity. Serum-sensitive *E. coli* organisms were killed by turkey serum treated with 10 mM ethylene glycol-bis-beta-(aminoethyl ether)-N,N,N',N'-tetraacetic acid and 5 mM MgCl₂. Exposure of normal turkey serum to serum-sensitive or serum-resistant *E. coli* resulted in equivalent reductions in hemolytic activity of serum. Treatment of serum-resistant *E. coli* with antibody rendered the bacteria sensitive to bactericidal effects of normal turkey serum. Serum-sensitive *E. coli* organisms were readily killed by an alternative complement pathway, serum-sensitive and serum-resistant *E. coli* activated the complement system equally well, and antibody was required for complement-mediated killing of certain serum-resistant *E. coli* organisms from turkeys.

AB Pectate lyase (PL) is the principal or sole enzyme responsible for maceration of plant tissue caused by most strains of soft-rotting pseudomonads. Production of PL in four out of 25 *Pseudomonas fluorescens* (or *P. marginalis*) strains examined was not induced by the enzyme substrate, polygalacturonate (PGA), but was induced by Ca-2+. These four strains produced 10 times more PL in medium containing 1 mM CaCl₂ than in one containing no CaCl₂ supplement. Over 86% of total PL produced by these strains in CaCl₂-supplemented medium was excreted into the culture fluid. Only a small portion (13%) of total PL produced by these strains in CaCl₂-deficient medium was detected in the extracellular fraction. Ca-2+ thus affected not only the amount but also the final destination of PL produced by these pseudomonads. Additionally, all four strains were

unable to use PGA as a nutritional source when cultured in Ca-2+-deficient medium, which indicates that the initial step of PGA degradation was mediated by Ca-2+-dependent PL and not by Ca-2+-independent polygalacturonase. The optimal Ca-2+ concentration required for PL production in one of these strains, CY091, was determined to be 0.2 mM. A linear correlation was observed between the amounts of PL produced and the concentrations of Ca-2+ included in the medium. Furthermore, the requirement of Ca-2+ for PL induction could be replaced by Sr-2+ but not by other divalent cations, such as Zn-2+, Fe-2+, Mn-2+, Mg-2+, and Ba-2+. Because of the indispensable role of Ca-2+ in PGA degradation and in PL production, the possibility of using the ion-chelating agent ethylenediaminetetraacetic acid (EDTA) for control of Pseudomonas rot was evaluated. **EDTA** exhibited **bactericidal** activity against *P. fluorescens* at a minimal inhibitory concentration of 4 mM. When assayed on potato tuber disks, EDTA at a concentration of 0.13 mM (40 ppm), which is 30-fold lower than the minimal inhibitory concentration, was effective in preventing *P. fluorescens* from growing and causing maceration in potato tuber tissue.

AB The relative roles of Kupffer cells, complement [C] and specific antibody in liver antimicrobial activities were investigated by using a rat liver perfusion model. Normal livers trapped an average of 60% of Salmonella typhimurium in a single pass and in the presence of plasma killed more than 60% of these organisms in 30 min. Livers depleted of Kupffer cell function by silica treatment had significantly less bactericidal ability (ca. [about] 15%) in the presence of plasma, showing that viable Kupffer cells are required for optimal antimicrobial activity. To determine the importance of C in Salmonella killing, plasma C activity was inhibited by heating at 57 and 50° C, zymosan absorption, chelation with disodium EDTA and depletion of rat C3 by using specific immunoabsorbent. All treatments significantly reduced bactericidal activity in the perfused liver. Chelation of plasma with EDTA had no effect, suggesting that the alternate and not the classical pathway for C activation was involved. Immune plasma alone was bactericidal. When immune plasma was heated, zymosan absorbed or chelated with **EDTA, bactericidal** activity was inhibited in the perfused liver but bacterial trapping increased. Complement may be required for bactericidal activity in perfused livers. Specific antibody may only enhance bacterial trapping.

AB Chelation of fresh human serum with 0.01 M MgCl₂ (Mg) plus 0.01 M ethylene glycol tetraacetic acid failed to abrogate the bactericidal activity against delayed serum-sensitive strains of S. marcescens: previously promptly serum-sensitive strains of S. marcescens and control strain Escherichia coli C were killed after an extended period of incubation. The addition of 0.01 M EDTA to fresh human serum neutralized bactericidal activity against S. marcescens of either serum sensitivity category.
